Write Abaqus Subroutines in Cython.

- GitHub repository: <https://github.com/haiiliin/abqcy>
- PyPI: <https://pypi.org/project/abqcy>
- Documentation: <https://abqcy.readthedocs.io>
- Read the Docs: <https://readthedocs.org/projects/abqcy>
- Bug report: <https://github.com/haiiliin/abqcy/issues>

## TABLE OF CONTENTS

### 1.1 Getting Started

abqcy allows you to write your Abaqus subroutines in [Cython](#). It provides a command line tool to compile your Cython code into an object file (`.obj`) that can be used by Abaqus.

#### 1.1.1 Installation

You can install abqcy with pip:

```
pip install abqcy
```

or install it from source:

```
pip install git+https://github.com/haiiliin/abqcy
```

#### 1.1.2 Environment Setup

abqcy requires a working Abaqus installation with user subroutines enabled. Make sure the `abaqus` command is available in the command line, otherwise you need to create a new system environment variable `ABAQUS_BAT_PATH` and set it to the path of the `abaqus.bat` file.

abqcy uses [Cython](#) to compile your Cython code into a C source file (`.c`). In order to compile the C source file into an object file (`.obj`) that can be used by Abaqus, the `abaqus make` command is used (it uses the MSVC `c1` compiler). Since the compiled `.c` file requires the Python headers and libraries, abqcy will try to find them automatically and update the `INCLUDE` and `LIB` environment variables. If it fails to find them, you need to update the `INCLUDE` and `LIB` environment variables manually.

#### 1.1.3 Usage

##### Compile the Subroutine

You can now write your Abaqus subroutine in Cython, simple scripts can be found in [Examples](#).

---

**Note:** In order to not mess up with the Cython declarations, you can add a companion `.pxd` file with the same name as your Cython `.py` or `.pyx` file, and put the Cython declarations in it. If you are not comfortable with keeping two files, you can just use the `.pyx` file with the Cython declarations.

See *Examples* for detailed examples.

---

After you have written your subroutine, you can compile it with the abqcy command:

```
abqcy compile <path-to-your-subroutine>
```

This will compile your subroutine into a C source file (.c) and a C header file (.h), and then they will be compiled into an object file (.obj) that can be used by Abaqus. These files are in the same directory as your subroutine.

Now you can use the subroutine in Abaqus, like:

```
abaqus job=Job-1 input=<model.inp> user=<subroutine>
```

### Run an Abaqus Job, Post-process and Visualize the Results in a Single Command

You can use the abqcy run command to run an Abaqus job with your subroutine, post-process the results and visualize them in a single command:

```
abqcy run <script-or-inp> --user=<subroutine> --job=<job-name> --output=<output-dir> --  
post=<post-process-script> --visualization=<visualization-script>
```

where:

- **script-or-inp**: a Python script (.py) file using the abaqus cae command to create the input file (.inp) or an input file (.inp) to run.
- **subroutine**: a Cython/Python file (py or pyx) or any other file that can be used by Abaqus as a user subroutine (.f, .for, .c, .cc, .cpp, .cxx). When using a Cython/Python file, the abqcy compile command will be used to compile it into an object file (.obj) before running the job.
- **job-name**: the name of the job to run. Defaults to the name of the input file.
- **output-dir**: the directory to store all the output files including models, subroutines, scripts, results, etc. Defaults to the current working directory.
- **post-process-script**: a Python script (.py) file to post-process the results using the abaqus cae command.
- **visualization-script**: a Python script (.py) file to visualize the results executed by the current Python interpreter.
- Additional flags are passed to the abaqus command.

See `abqcy.cli.AbqcyCLI.run()` method for more details.

## 1.2 Tutorial

This page is a tutorial for the abqcy project. It will guide you through the whole workflow of using abqcy to write an Abaqus user subroutine, create the model, extract the output data, and visualize the results in a single command.

```

4  cdef extern from "<aba_for_c.h>":
5      pass
6
7
8  @cython.infer_types(True) # type: ignore
9  cdef extern void umat(
10     double *stress, double *statev, double *ddsdde, double *sse, double *spd,
11     double *scd, double *rpl, double *ddsdtt, double *drplde, double *drpldt,
12     double *stran, double *dstran, double *time, double *dtime, double *temp,
13     double *dtemp, double *predef, double *dpred, char *cmname, int *ndi,
14     int *nsh, int *ntens, int *nstatv, double *props, int *nprops, double *coords,
15     double *drot, double *pnweld, double *celent, double *dfgrd0, double *dfgrd1,
16     int *noel, int *npt, int *layer, int *kspt, int *jstep, int *kinc,
17 ):
18     E, nu = props[0], props[1]
19     lam = E * nu / ((1.0 + nu) * (1.0 - 2.0 * nu))
20     G = E / (2.0 * (1.0 + nu))
21
22     ddsdde[:, :] = [
23         lam + 2.0 * G, lam, lam, 0.0, 0.0, 0.0,
24         lam, lam + 2.0 * G, lam, 0.0, 0.0, 0.0,
25         lam, lam, lam + 2.0 * G, 0.0, 0.0, 0.0,
26         0.0, 0.0, 0.0, G, 0.0, 0.0,
27         0.0, 0.0, 0.0, 0.0, G, 0.0,
28         0.0, 0.0, 0.0, 0.0, 0.0, G,
29         # ... more entries ...
30     ]

```

### 1.2.1 1. Write the user subroutine

The Abaqus user subroutine can be written in a Cython file. The subroutine is very similar to a Abaqus C/C++ subroutine, except that it is written in Cython syntax. Check [Examples](#) for some simple examples.

### 1.2.2 2. Create the model as an Abaqus input file

You can use the Python script to create an Abaqus model, check [abqpy tutorials](#) for a simple example. Noted that in the Python script, you should save the model into an Abaqus input file (`.inp`), so that the abqcy can read the model from the input file. For example:

```

# Job
job = mdb.Job(name="element", model="Model-1")
job.writeInput()

```

If you are not familiar with Abaqus Python scripting, you can also use the Abaqus/CAE GUI to create an input file directly.

### 1.2.3 3. Write Python script to extract the output data from the Abaqus output database

You can use the Python script to extract the output data from the Abaqus output database (.odb). You can also find a simple example in the [abqpy tutorials](#). Typically, this Python script will extract the output data from the Abaqus output database and save it into a data file

### 1.2.4 4. Visualize the results

Data extracted from the Abaqus output database can be visualized using another Python script. For example, you can use the [matplotlib](#) library to plot the data.

### 1.2.5 5. Run the abqcy command

After all the above steps are completed, you can run the `abqcy run` to finish the whole workflow:

```
abqcy run --model=<script-or-inp> --user=<subroutine> --post=<script> --visualiation=
˓→<script>
```

In chronological order, the `abqcy run` command will:

- Generate an Abaqus input file from the Python script, if the `--model` option is a Python script.
- Compile the user subroutine to an object file (.obj), if the `--user` option is a Cython file.
- Run the Abaqus analysis with the `abaqus input=<inp> user=<obj>` command.
- Run the post-processing Python script with the `abaqus cae noGUI=<script>` command.
- Run the visualization Python script with the `python <script>` command, using the Python interpreter (instead of the Abaqus command) to visualize the results.

### 1.2.6 Example

The following is an example of scripts required by the `abqcy run` command:

```
1 import cython
2
3
4 cdef extern from "<aba_for_c.h>":
5     pass
6
7
8 @cython.infer_types(True) # type: ignore
9 cdef extern void umat(
10     double *stress, double *statev, double *ddsdde, double *sse, double *spd,
11     double *scd, double *rpl, double *ddsddt, double *drplde, double *drpldt,
12     double *stran, double *dstran, double *time, double *dtime, double *temp,
13     double *dtemp, double *predef, double *dpred, char *cmname, int *ndi,
14     int *nshr, int *ntens, int *nstatv, double *props, int *nprops, double *coords,
15     double *drot, double *pnewdt, double *celent, double *dfgrd0, double *dfgrd1,
16     int *noel, int *npt, int *layer, int *kspt, int *jstep, int *kinc,
17 ):
```

(continues on next page)

(continued from previous page)

```

18     E, nu = props[0], props[1]
19     lam = E * nu / ((1.0 + nu) * (1.0 - 2.0 * nu))
20     G = E / (2.0 * (1.0 + nu))
21
22     ddsdde[:] = [
23         lam + 2.0 * G, lam, lam, 0.0, 0.0, 0.0,
24         lam, lam + 2.0 * G, lam, 0.0, 0.0, 0.0,
25         lam, lam, lam + 2.0 * G, 0.0, 0.0, 0.0,
26         0.0, 0.0, 0.0, G, 0.0, 0.0,
27         0.0, 0.0, 0.0, 0.0, G, 0.0,
28         0.0, 0.0, 0.0, 0.0, 0.0, G,
29     ] # fmt: skip
30     for i in range(6):
31         for j in range(6):
32             stress[i] += ddsdde[6 * i + j] * dstran[j]

```

```

```

```

1 import matplotlib.pyplot as plt
2 import pandas as pd
3
4 U3 = pd.read_csv("U3.csv")
5
6 fig, ax = plt.subplots()
7 ax.plot(U3["time"], U3["U3"])
8 ax.set_xlabel("Time (s)")
9 ax.set_ylabel("Displacement (m)")
10 ax.grid()
11 fig.savefig("U3.png", bbox_inches="tight", pad_inches=0.1)

```

```

1 abqcy run --model=element.py --user=elastic.pyx --post=element-output.py --
2   --visualization=element-visualization.py

```

**Note:** You can check all the files in the `docs/tutorials` folder of the `abqcy` repository.

## 1.3 Examples

Below are some examples of how to use the library. To compile the examples into an object file (.obj) that can be used by Abaqus, you can run the following command:

```
abqcy compile <path-to-your-subroutine>
```

**Note:** It should be noted that temporary variables do not require to be typed in Cython except for integers. In the following examples, the `cython.infer_types` directive is used to infer types of untyped variables in function bodies including integers. This directive does a work similar to the `auto` keyword in C++ for the readers who are familiar with this language feature. It can be of great help to cut down on the need to type everything, but it also can lead to surprises.

See [Determining where to add types](#) for more information.

### 1.3.1 Example: Elastic umat subroutine

This example shows how to write an Abaqus elastic umat subroutine in Cython.

```

1 import cython
2
3
4 cdef extern from "<aba_for_c.h>":
5     pass
6
7
8 @cython.infer_types(True) # type: ignore
9 cdef extern void umat(
10     double *stress, double *statev, double *ddsdde, double *sse, double *spd,
11     double *scd, double *rpl, double *ddssdt, double *drplde, double *drpldt,
12     double *stran, double *dstran, double *time, double *dtime, double *temp,
13     double *dtemp, double *predef, double *dpred, char *cmname, int *ndi,
14     int *nshr, int *ntens, int *nstatv, double *props, int *nprops, double *coords,
15     double *drot, double *pnnewdt, double *celent, double *dfgrd0, double *dfgrd1,
16     int *noel, int *npt, int *layer, int *kspt, int *jstep, int *kinc,
17 ):
18     E, nu = props[0], props[1]
19     lam = E * nu / ((1.0 + nu) * (1.0 - 2.0 * nu))
20     G = E / (2.0 * (1.0 + nu))
21
22     ddsdde[:] = [
23         lam + 2.0 * G, lam, lam, 0.0, 0.0, 0.0,
24         lam, lam + 2.0 * G, lam, 0.0, 0.0, 0.0,
25         lam, lam, lam + 2.0 * G, 0.0, 0.0, 0.0,
26         0.0, 0.0, 0.0, G, 0.0, 0.0,
27         0.0, 0.0, 0.0, 0.0, G, 0.0,
28         0.0, 0.0, 0.0, 0.0, 0.0, G,
29     ] # fmt: skip
30     for i in range(6):
31         for j in range(6):
32             stress[i] += ddsdde[6 * i + j] * dstran[j]
```

```

1 import cython
2
3
4 @cython.infer_types(True) # type: ignore
5 def umat(
6     stress, statev, ddsdde, sse, spd, scd, rpl, ddssdt, drplde, drpldt, stran, dstran,
7     time, dtime, temp, dtemp, predef, dpred, cmname, ndi, nshr, ntens, nstatv, props,
8     nprops, coords, drot, pnnewdt, celent, dfgrd0, dfgrd1, noel, npt, layer, kspt,
9     jstep, kinc,
10 ): # fmt: skip
11     E, nu = props[0], props[1]
12     lam = E * nu / ((1.0 + nu) * (1.0 - 2.0 * nu))
13     G = E / (2.0 * (1.0 + nu))
14
15     ddsdde[:] = [
16         lam + 2.0 * G, lam, lam, 0.0, 0.0, 0.0,
```

(continues on next page)

(continued from previous page)

```

17     lam, lam + 2.0 * G, lam, 0.0, 0.0, 0.0,
18     lam, lam, lam + 2.0 * G, 0.0, 0.0, 0.0,
19     0.0, 0.0, 0.0, G, 0.0, 0.0,
20     0.0, 0.0, 0.0, 0.0, G, 0.0,
21     0.0, 0.0, 0.0, 0.0, 0.0, G,
22 ] # fmt: skip
23 for i in range(6):
24     for j in range(6):
25         stress[i] += ddsdde[6 * i + j] * dstran[j]

```

**Note:** You will need to add the Cython header file (.pxd) along with the Python file (.py) in order to use the Cython declarations.

```

1 cdef extern from "<aba_for_c.h>":
2     pass
3
4
5 cdef extern void umat(
6     double *stress, double *statev, double *ddsdde, double *sse, double *spd,
7     double *scd, double *rpl, double *ddsdde, double *drplde, double *drpldt,
8     double *stran, double *dstran, double *time, double *dtime, double *temp,
9     double *dtemp, double *predef, double *dpred, char *cmname, int *ndi,
10    int *nshr, int *ntens, int *nstatv, double *props, int *nprops, double *coords,
11    double *drot, double *pnewdt, double *celent, double *dfgrd0, double *dfgrd1,
12    int *noel, int *npt, int *layer, int *kspt, int *jstep, int *kinc,
13 )

```

**Note:** This file is required to use the Cython declarations in the Python file (.py).

## 1.4 Command Line Interface

The abqcy command line is used to compile your Cython code into an object (.obj) file that can be used by Abaqus. You can use it in the command line or in a Python script with the `abqcy.cli.abqcy` object (an `abqcy.cli.AbqcyCLI` object).

### 1.4.1 References

#### The abqcy command (`abqcy.cli.AbqcyCLI`)

```

$ abqcy
NAME
    abqcy - The ``abqcy`` command-line interface.

SYNOPSIS
    abqcy COMMAND

```

(continues on next page)

(continued from previous page)

**DESCRIPTION**

The ``abqcy`` command-line interface.

**COMMANDS**

COMMAND is one of the following:

compile

Compile a Cython script to an Abaqus user subroutine as an object file.

run

Run Abaqus jobs.

**The abqcy compile command (abqcy.cli.AbqcyCLI.compile())**

```
$ abqcy compile --help
```

```
INFO: Showing help with the command 'abqcy compile -- --help'.
```

**NAME**

```
abqcy compile - Compile a Cython script to an Abaqus user subroutine as an object_  
file.
```

**SYNOPSIS**

```
abqcy compile SCRIPT <flags>
```

**DESCRIPTION**

Compile a Cython script to an Abaqus user subroutine as an object file.

**POSITIONAL ARGUMENTS**

SCRIPT

Type: 'str'

The path to the Cython script to compile.

**FLAGS**

--exclude=EXCLUDE

Type: Optional['list']

Default: None

When passing glob patterns as ``script``, you can exclude certain module names\_  
explicitly by passing them into the ``exclude`` option.

-n, --nthreads=NTHREADS

Type: 'int'

Default: 0

The number of concurrent builds for parallel compilation (requires the\_  
``multiprocessing`` module).

--aliases=ALIASES

Type: Optional['dict']

Default: None

If you want to use compiler directives like ``# distutils: ...`` but can only\_  
know at compile time (when running the ``setup.py``) which values to use, you can use\_  
aliases and pass a dictionary mapping those aliases

(continues on next page)

(continued from previous page)

```

-q, --quiet=QUIET
    Type: 'bool'
    Default: False
    If True, Cython won't print error, warning, or status messages during the
compilation.

-f, --force=FORCE
    Type: 'bool'
    Default: False
    Forces the recompilation of the Cython modules, even if the timestamps don't
indicate that a recompilation is necessary.

-l, --language=LANGUAGE
    Type: Optional['str']
    Default: None
    To globally enable C++ mode, you can pass ``language='c++'``. Otherwise, this
will be determined at a per-file level based on compiler directives. This affects
only modules found based on file names. Extension instances passed

--exclude_failures=EXCLUDE_FAILURES
    Type: 'bool'
    Default: False
    For a broad 'try to compile' mode that ignores compilation failures and simply
excludes the failed extensions, pass ``exclude_failures=True``. Note that this only
really makes sense for compiling ``.py`` files which can also be used without
compilation.

--annotate=ANNOTATE
    Type: 'bool'
    Default: True
    Whether to generate an HTML file with annotations, by default True.

Additional flags are accepted.

    Additional keyword arguments to pass to the ``cythonize`` function.

```

**NOTES**

You can also use flags syntax for POSITIONAL ARGUMENTS

**The abqcy run command (abqcy.cli.AbqcyCLI.run())**

```

$ abqcy run --help
INFO: Showing help with the command 'abqcy run -- --help'.

NAME
    abqcy run - Run Abaqus jobs.

SYNOPSIS
    abqcy run MODEL <flags>

DESCRIPTION
    Run Abaqus jobs.

POSITIONAL ARGUMENTS
    MODEL
        Type: 'str'

```

(continues on next page)

(continued from previous page)

The path to the input file or a Python script to create the input file.

**FLAGS**

-u, --user=USER

Type: Optional['str']

Default: None

The name of the user subroutine, if it is a Cython/Pure Python script, it will

be compiled to an object file automatically. If a companion ``.pxd`` file is found, it will be copied to the output directory along with the Cython/Pure Python script.

-j, --job=JOB

Type: Optional['str']

Default: None

The name of the job, by default the model name without the extension.

-o, --output=OUTPUT

Type: Optional['str']

Default: None

The path to the output directory, by default the current directory.

-p, --post=POST

Type: Optional['str']

Default: None

The Python script to run after finishing the job to post-process the results. In

the output script, a placeholder ``{odb}`` will be replaced with the path to the output database file.

-v, --visualization=VISUALIZATION

Type: Optional['str']

Default: None

The Python script to run after finishing the job to visualize the results.

Typically, this script will plot a figure based on the data saved by the post-processing script.

Additional flags are accepted.

Additional keyword arguments to pass to the ``abaqus`` command to run the job.

**NOTES**

You can also use flags syntax for POSITIONAL ARGUMENTS

#### Attributes

<code>abqcy</code>
--------------------

### `class AbqcyCLI`

The abqcy command-line interface.

#### `_update_include_lib()`

Update the INCLUDE and LIB environment variables.

`compile(script: str, *, exclude: list = None, nthreads: int = 0, aliases: dict = None, quiet: bool = False, force: bool = False, language: str = None, exclude_failures: bool = False, annotate: bool = True, **kwargs)`

Compile a Cython script to an Abaqus user subroutine as an object file.

#### Parameters

- **script** (`str`) – The path to the Cython script to compile.
- **exclude** (`list, optional`) – When passing glob patterns as `script`, you can exclude certain module names explicitly by passing them into the `exclude` option.
- **nthreads** (`int, optional`) – The number of concurrent builds for parallel compilation (requires the `multiprocessing` module).
- **aliases** (`dict, optional`) – If you want to use compiler directives like `# distutils: ...` but can only know at compile time (when running the `setup.py`) which values to use, you can use aliases and pass a dictionary mapping those aliases to Python strings when calling `cythonize()`. As an example, say you want to use the compiler directive `# distutils: include_dirs = ../../staticlibs/include/` but this path isn't always fixed and you want to find it when running the `setup.py`. You can then do `# distutils: include_dirs = MY_HEADERS`, find the value of `MY_HEADERS` in the `setup.py`, put it in a python variable called `foo` as a string, and then call `cythonize(.., aliases={'MY_HEADERS': foo})`.
- **quiet** (`bool, optional`) – If True, Cython won't print error, warning, or status messages during the compilation.
- **force** (`bool, optional`) – Forces the recompilation of the Cython modules, even if the timestamps don't indicate that a recompilation is necessary.

- **language** (*str, optional*) – To globally enable C++ mode, you can pass `language='c++'`. Otherwise, this will be determined at a per-file level based on compiler directives. This affects only modules found based on file names. Extension instances passed into `cythonize()` will not be changed. It is recommended to rather use the compiler directive `# distutils: language = c++` than this option.
- **exclude\_failures** (*bool, optional*) – For a broad ‘try to compile’ mode that ignores compilation failures and simply excludes the failed extensions, pass `exclude_failures=True`. Note that this only really makes sense for compiling .py files which can also be used without compilation.
- **annotate** (*bool, optional*) – Whether to generate an HTML file with annotations, by default True.
- **kwarg**s – Additional keyword arguments to pass to the `cythonize` function.

**run**(*model: str, \*, user: str = None, job: str = None, output: str = None, post: str = None, visualization: str = None, \*\*kwargs*)

Run Abaqus jobs.

#### Parameters

- **model** (*str*) – The path to the input file or a Python script to create the input file.
- **user** (*str*) – The name of the user subroutine, if it is a Cython/Pure Python script, it will be compiled to an object file automatically. If a companion .pxd file is found, it will be copied to the output directory along with the Cython/Pure Python script.
- **job** (*str, optional*) – The name of the job, by default the model name without the extension.
- **output** (*str, optional*) – The path to the output directory, by default the current directory.
- **post** (*str, optional*) – The Python script to run after finishing the job to post-process the results. In the output script, a placeholder `{odb}` will be replaced with the path to the output database file.
- **visualization** (*str, optional*) – The Python script to run after finishing the job to visualize the results. Typically, this script will plot a figure based on the data saved by the post-processing script.
- **kwarg**s – Additional keyword arguments to pass to the `abaqus` command to run the job.
